5.1.2.1 BFLBody::BFLBody (void)

Default constructor.

5.1.2.2 BFLBody::~BFLBody (void)

Default destructor.

5.1.2.3 BFLBody::BFLBody (PCpts * *_PCpts,* GridObj * *g_hierarchy,* size_t *id*)

Custom constructor to populate body from array of points.

Parameters

_PCpts	pointer to point cloud data
g_hierarchy	pointer to grid hierarchy
id	ID of body in array of bodies.

5.1.3 Member Function Documentation

5.1.3.1 void BFLBody::computeQ (int *i,* int *j,* int *k,* GridObj * *g*) [protected]

Routine to compute wall distance Q.

Computes Q values in 3D at a given local voxel for each application of the BFL BC. Performs a line-plane intersection algorithm for every possible triangular plane constructed out of the marker in the voxel and its nearest neighbours.

Parameters

i	local i-index of BFL voxel
j	local j-index of BFL voxel
k	local k-index of BFL voxel
g	pointer to owner grid

5.1.3.2 void BFLBody::computeQ (int *i*, int *j*, GridObj * *g*) [protected]

Routine to compute wall distance Q.

Computes Q values in 2D at a given local voxel for each application of the BFL BC. Performs a line-line intersection algorithm for each line segment either side of the voxel marker.

Parameters

i	local i-index of BFL voxel
j	local j-index of BFL voxel
g	pointer to owner grid

Velocity in lattice units to velocity in physical units.

You can introduce any L_PHYSICAL_U you want, but the reference lenght (usualy the width of the domain) , the Re number and the LBM parameters will remain the same. So you will be implicitly changing the physical viscosity of your fluid when you change L_PHYSICAL_U

Parameters

5.14.1 Detailed Description

MPI Manager class.

Class to manage all MPI apsects of the code.

5.14.2 Member Function Documentation

5.14.2.1 void MpiManager::destroyInstance ( ) [static]

Instance destroyer.

5.14.2.2 MpiManager * MpiManager::getInstance ( ) [static]

Instance creator.

5.14.2.3 void MpiManager::mpi_buffer_pack (int *dir*, GridObj * *g*)

Method to pack the communication buffer.

Communication buffer is packed with distribution values from the supplied grid. Amount of information is dictated by the direction of the communication being prepared.

Parameters

dir	communication direction.
g	grid doing the communication.

5.14.2.4 void MpiManager::mpi_buffer_size ( )

Pre-calcualtion of the buffer sizes.

Wrapper method for computing the buffer sizes for every grid on the rank, both sender and receiver. Must be called post-initialisation.

5.14.2.5 void MpiManager::mpi_buffer_size_recv (GridObj *& *g*)

Method to pre-compute the size of the receiver layer buffer.

A halo consists of a receiver (outer) and sender (inner) layer. This method computes the size of the receiver layers in each communication direction (MPI directions).

Parameters

g	grid being inspected.

5.14.2.6 void MpiManager::mpi_buffer_size_send (GridObj *& *g*)

Method to pre-compute the size of the sender layer buffer.

A halo consists of a receiver (outer) and sender (inner) layer. This method computes the size of the sender layers in each communication direction (MPI directions).

Parameters

g	grid being inspected.

5.14.2.7 void MpiManager::mpi_buffer_unpack (int *dir,* GridObj * *g*)

Method to unpack the communication buffer.

Communication buffer is unpacked onto the supplied grid. Amount and region of unpacking is dictated by the direction of the communication taking place.

Parameters

dir	communication direction.
g	grid doing the communication.

5.14.2.8 int MpiManager::mpi_buildCommunicators ( )

Define writable sub-grid communicators.

When using HDF5 in parallel, collective IO operations require all processes to write a non-zero amount of data to the same file. This method examines availability of sub-grid and writable data on the grid (if found) and ensures it is added to a new communicator. Must be called AFTER the grids and buffers have been initialised.

5.14.2.9 void MpiManager::mpi_communicate (int *lev*, int *reg*)

Communication routine.

This method implements the communication between grids of the same level and region across MPI processes. Each call effects communication in all valid directions for the grid of the supplied level and region.

Parameters

lev	level of grid to communicate.
reg	region number of grid to communicate.

5.14.2.10 int MpiManager::mpi_getOpposite (int *direction*)

Helper method to find opposite direction in MPI topology.

The MPI directional vectors do not necessarily correspond to the lattice model direction. The MPI directional vectors are defined separately and hence there is a separate opposite finding method.

Parameters

direction	the outgoing direction whose opposite you wish to find.

5.14.2.11 void MpiManager::mpi_gridbuild ( )

Domain decomposition.

Method to decompose the domain and identify local grid sizes. Parameters defined here are used in GridObj construction.

5.14.2.12 void MpiManager::mpi_init ( )

Initialisation routine.

Method is responsible for initialising the MPI topolgy and associated data. Must be called immediately after MPI_↩ init().

5.14.2.13 void MpiManager::mpi_updateLoadInfo ( )

Update the load balancing information stored in the MpiManager.

This method is executed by all processes. Counts the ACTIVE cells on the current rank and pushes the information to the master (rank 0) which writes this information to an output file if required. Must be called after the grids have been built or will return zero.

5.14.2.14 void MpiManager::mpi_writeout_buf (std::string *filename,* int *dir*)

Buffer ASCII writer.

When verbose MPI logging is turned on this method will write out the communication buffer to an ASCII file.

Perform IBM procedure.

5.15.2.8 void ObjectManager::ibm_banbks (double ** *a*, long *n*, int *m1*, int *m2*, double ** *al*, unsigned long *indx[]*, double *b[]*)

Solution of a banded diagonal linear system.

Given the arrays A, AL, and INDX as returned from ibm_bandec(), and given a right-hand side vector B[1..n], solves the band diagonal linear equations AX = B. The solution vector X overwrites B. The other input arrays are not modified, and can be left in place for successive calls with different right-hand sides. (C) Copr. 1986-92 Numerical Recipes Software ?421.1-9.

Parameters

a	array of subdiagonal and superdiagonals rows
n	size of the square matrix A
m1	number of subdiagonal rows
m2	number of superdiagonal rows
al	lower triangular matrix
indx	row permutation vector
b	right hand side vector

5.15.2.9 void ObjectManager::ibm_bandec (double ** *a*, long *n*, int *m1*, int *m2*, double ** *al*, unsigned long *indx[]*, double * *d*)

LU decomposition of band diagonal matrix.

Given an n by n band diagonal matrix A with m1 subdiagonal rows and m2 superdiagonal rows, compactly stored in the array A[1..n][1..m1+m2+1] , this routine constructs an LU decomposition of a rowwise permutation of A. The upper triangular matrix replaces A, while the lower triangular matrix is returned in AL[1..n][1..m1]. INDX[1..n] is an output vector which records the row permutation effected by the partial pivoting; D is output as +/-1 depending on whether the number of row interchanges was even or odd, respectively. This routine is used in combination with ibm_banbks() to solve band-diagonal sets of equations. Once the matrix A has been decomposed, any number of right-hand sides can be solved in turn by repeated calls to ibm_banbks(). (C) Copr. 1986-92 Numerical Recipes Software ?421.1-9.

n	size of the square matrix A
